# 1 Syntax

## 1.1 Metavariables

Below is a list of meta-variables for different fundamental language constructs

$x \in Var$	Variable identifier
$b \in \{true, false\}$	Boolean
$n \in \mathbb{N}$	Natural number
$s \in \Sigma^*$	String
$\oplus \in \{+, -, *, /, \%, <, >, <=, >=, ==\}$	Binary operator
$!, =\}$	Unary operator

## 1.2 Expressions

$\langle e \rangle ::= n$	Integer
$b$	Boolean
$s$	String
$()$	Nothing
$x$	Identifier
$e_1 \oplus e_2$	Binary Operation
$(e_1, e_2, \dots, e_n)$	Vector
$[]$	Nil (empty list)
$e_1 :: e_2$	Cons (nonempty list)
<b>fn</b> $p \rightarrow e$	Function
<b>bind</b> $p \leftarrow e_1$ <b>in</b> $e_2$	Bind expression
<b>bind</b> $p \ p_1 \dots p_n \leftarrow e_1$ <b>in</b> $e_2$	Bind expression
<b>bind rec</b> $f \leftarrow \text{fn } p \rightarrow e_1$ <b>in</b> $e_2$	Recursive function
<b>bind rec</b> $f \ p_1 \dots p_n \leftarrow e_1$ <b>in</b> $e_2$	Recursive function
$e_1 \ e_2$	Function application
<b>if</b> $e_1$ <b>then</b> $e_2$ <b>else</b> $e_3$	Ternary expressions
<b>switch</b> $e_0 \Rightarrow$   $p_1 \rightarrow e_1 \dots$   $p_n \rightarrow e_n$ <b>end</b>	Switch expression

### 1.3 Patterns

$\langle p \rangle ::=$	$\_$	Wildcard pattern*
	$x$	Identifier pattern**
	$()$	Nothing pattern
	$b$	Boolean pattern
	$n$	Integer pattern
	$s$	String pattern
	$(p_1, p_2, \dots, p_n)$	Vector pattern
	$[]$	Nil pattern
	$p_1 :: p_2$	Cons pattern***

\* The wildcard pattern matches any value

\*\* The identifier pattern matches any value and produces a binding to it

\*\*\* The cons pattern matches a non empty list, but only  $p_1$  matches the head of the list and  $p_2$  matches the remainder of the list

### 1.4 Values

$\langle v \rangle ::=$	$n$	Integer value
	$s$	String value
	$b$	Boolean value
	$()$	Nothing value
	$[]$	Nil value
	$v_1 :: v_2$	Cons value
	$(\Delta, p, e)$	Function Closure

### 1.5 Types

$\langle t \rangle ::=$	$\text{int}$	Integer type
	$\text{bool}$	Boolean type
	$\text{str}$	String type
	$\text{ng}$	Nothing type
	$t_i$	Type variable
	$t_1 \rightarrow t_2$	Function type*
	$[t]$	List type
	$(t_1, t_2, \dots, t_n)$	Vector type
	$(t)$	Parenthesized type*

\* The function type operator  $\rightarrow$  associates to the right

For example, the type  $t_1 \rightarrow t_2 \rightarrow t_3$  is parsed as  $t_1 \rightarrow (t_2 \rightarrow t_3)$

Parentheses are the highest precedence operator in the type grammar, and they can be used to counter the right associativity of the arrow operator.

For example

$$\text{fn } f \rightarrow \text{fn } x \rightarrow f\ x : (t_1 \rightarrow t_2) \rightarrow t_1 \rightarrow t_2$$

## 2 Dynamic Semantics

In order to discuss the dynamic semantics of the programming language, we first need to define a few things.

### 2.1 Dynamic Environment

LambdaScript uses an environment model to make substitutions in function bodies. The environment is an object defined as follows

$$\Delta \in Var \rightarrow Value$$

It is essentially a function from a set of variable identifiers to a set of values. Note that it is a partial function because its domain will be a subset of  $Var$

- $\Delta(x)$  represents the value  $x$  maps to in environment  $\Delta$
- $\{\}$  is the empty environment
- $\Delta[x \rightarrow v]$  represents the environment where  $\Delta(y) = v$  if  $y = x$ , and  $\Delta(y)$  otherwise
- $D(\Delta)$  is the domain of  $\Delta$
- $\Delta_1 \circ \Delta_2$  represents the environment  $\Delta$  where  $\forall y \in D(\Delta_2), \Delta(y) = \Delta_2(y), \forall y \in D(\Delta_1) - D(\Delta_2), \Delta(y) = \Delta_1(y)$ . Otherwise,  $\Delta(y)$  is not defined.

### 2.2 Evaluation Relation

The evaluation relation is what describes how an expression is evaluated to a value under a certain environment

Define it as follows

$$(\Delta, e) \Rightarrow v$$

It means the following: Under environment  $\Delta$ , expression  $e$  evaluates to value  $v$

### 2.3 Pattern Matching Relation

In order to model a value matching some pattern, and producing some bindings, we will use the following relation

$$v \in p \rightarrow \Delta$$

This can be read as "value  $v$  matches pattern  $p$  and produces bindings  $\Delta$ "

We will also use the following relation

$$v \notin p$$

This can be read as "value  $v$  does not patch pattern  $p$ "

Below are the semantics for each pattern

Wildcard

$$v \in \_ \rightarrow \{\}$$

Variable Identifier

$$v \in x \rightarrow \{ \}[x \rightarrow v]$$

Nothing

$$() \in () \rightarrow \{\}$$

Boolean

$$b \in b \rightarrow \{\}$$

Integer

$$i \in i \rightarrow \{\}$$

String

$$s \in s \rightarrow \{\}$$

Nil / Empty List

$$[] \in [] \rightarrow \{\}$$

## Vector

$$(v_1, v_2, \dots, v_n) \in (p_1, p_2, \dots, p_n) \rightarrow \Delta_1 \circ \Delta_2 \circ \dots \circ \Delta_n$$

---

$$v_1 \in p_1 \rightarrow \Delta_1$$

$$v_2 \in p_2 \rightarrow \Delta_2$$

...

$$v_n \in p_n \rightarrow \Delta_n$$

Cons

$$v_1 :: v_2 \in p_1 :: p_2 \rightarrow \Delta_1 \circ \Delta_2$$

---

$$v_1 \in p_1 \rightarrow \Delta_1$$

$$v_2 \in p_2 \rightarrow \Delta_2$$

## 2.4 Basic Dynamic Semantics

### 2.4.1 Value

$$(\Delta, v) \Rightarrow v$$

A value always evaluates to itself

### 2.4.2 Variable Identifiers

$$(\Delta, x) \Rightarrow \Delta(x)$$

To evaluate an identifier  $x$ , it is simply looked up in the environment  $\Delta$

### 2.4.3 Vector

$$(\Delta, (e_1, e_2, \dots, e_n)) \Rightarrow (v_1, v_2, \dots, v_n)$$

---

$$(\Delta, e_1) \Rightarrow v_1$$

$$(\Delta, e_2) \Rightarrow v_2$$

...

$$(\Delta, e_n) \Rightarrow v_n$$

To evaluate a vector, evaluate each sub expression, then construct a new vector with the values

#### 2.4.4 Cons

$$(\Delta, e_1 :: e_2) \Rightarrow v_1 :: v_2$$

---

$$(\Delta, e_1) \Rightarrow v_1$$

$$(\Delta, e_2) \Rightarrow v_2$$

To evaluate a cons expression, evaluate the two operands, then return the first argument prepended to the second

### 2.5 Switch Statement Semantics

A switch statement uses an expression, call it  $e_0$  and a list of branches. Each branch consists of a pattern and a body.

First,  $e_0$  is evaluated to a value  $v_0$  using the current environment  $\Delta$

Starting from the first branch,  $v_0$  is compared to its pattern. If it matches, certain bindings are produced, which are used to evaluate its body. That value is then returned.

This process of comparing  $v_0$  to the pattern of a branch continues until a match is made.

$$(\Delta, \text{switch } e \Rightarrow |p_1 \rightarrow e_1 \dots |p_n \rightarrow e_n \text{ end}) \Longrightarrow v'$$

---

$$(\Delta, e) \Longrightarrow v$$

$$v \notin p_i \text{ for } i < m$$

$$v \in p_m \rightarrow \Delta_m \text{ where } 1 \leq m \leq n$$

$$(\Delta \circ \Delta_m, e_j) \Longrightarrow v'$$

Let's go through those statements one by one

1.  $(\Delta, e) \Longrightarrow v$  shows that  $e$  evaluates to  $v$  under environment  $\Delta$
2.  $v \notin p_i$  for  $i < m$  shows that  $v$  doesn't match the first  $m - 1$  patterns
3.  $v \in p_m \rightarrow \Delta_m$  where  $1 \leq m \leq n$  shows that  $v$  matches the  $m^{\text{th}}$  pattern and produces bindings  $\Delta_m$
4.  $(\Delta \circ \Delta_m, e_m) \Longrightarrow v'$  shows that the body of the  $m^{\text{th}}$  branch evaluates to a value  $v'$  under the external environment  $\Delta$  composed with the new bindings  $\Delta_m$ .  $v'$  is what the entire switch expression evaluates to.

## 2.6 Ternary Expression

There are two rules regarding the dynamic semantics of ternary expressions. There is one for when the predicate is true and one for when the predicate is false.

$$\begin{array}{c}
 (\Delta, \text{if } e_1 \text{ then } e_2 \text{ else } e_3) \Longrightarrow v \\
 \hline
 (\Delta, e_1) \Longrightarrow \text{true} \\
 (\Delta, e_2) \Longrightarrow v \\
 \hline
 (\Delta, \text{if } e_1 \text{ then } e_2 \text{ else } e_3) \Longrightarrow v \\
 \hline
 (\Delta, e_1) \Longrightarrow \text{false} \\
 (\Delta, e_3) \Longrightarrow v
 \end{array}$$

## 2.7 Function

A function in LambdaScript evaluates to a function closure, which consists of three parts: the environment, the pattern, and the body.

$$(\Delta, \text{fn } p \rightarrow e) \Longrightarrow (\Delta, p, e)$$

## 2.8 Function Application

$$\begin{array}{c}
 (\Delta, e_1 \ e_2) \Longrightarrow v \\
 \hline
 (\Delta, e_1) \Longrightarrow (\Delta_c, p_c, e_c) \\
 (\Delta, e_2) \Longrightarrow v_2 \\
 v_2 \in p_c \Longrightarrow \Delta_n \\
 (\Delta_c \circ \Delta_n, e_c) \Longrightarrow v
 \end{array}$$

Let's go through these statements one by one

1.  $(\Delta, e_1) \Longrightarrow (\Delta_c, p_c, e_c)$  states that  $e_1$  evaluates to a function closure. This is crucial because if  $e_1$  is not a function closure, it cannot be applied.

2.  $(\Delta, e_2) \implies v_n$  states that  $e_2$ , the argument, evaluates to a value  $v_2$
3.  $v_2 \in p_c \implies \Delta_2$  states that  $v_2$ , the value of the argument, matches the pattern of the function closure  $p_c$  and produces bindings  $\Delta_n$
4.  $(\Delta_c \circ \Delta_n, e_c) \implies v$  states that  $e_c$ , the body of the function closure, evaluates to a value  $v$  under the environment of the function closure,  $\Delta_c$  composed with the new bindings  $\Delta_n$ , which result from matching the value of the argument  $v$  against the pattern  $p_c$ . The entire expression evaluates to  $v$ .

### 3 Static Semantics
